# FLIPKART SALES REPORT

*Tracking Best-Sellers, Sales Trends, Ratings, Regional Demand & Inventory*

**Note on data:** Flipkart's live transaction data isn't publicly accessible, so this report uses a synthetic dataset built to mirror real e-commerce patterns — 60 products across 10 categories, 8 regions, 30 days, ~5 million simulated units. It shows exactly what a descriptive analytics pipeline processing millions of daily purchases would produce; the same structure applies once real data is substituted in.

## 1. Executive Summary

This report simulates a descriptive analytics layer over daily e-commerce purchase transactions at Flipkart-scale, covering 60 products across 10 categories, 8 regions, and a 30-day window (~4.99M units, ~\$623M in revenue). It is built to demonstrate the exact structure, charts, and metrics a real analytics pipeline would produce once connected to live transaction data.

Five recurring business questions anchor the analysis: what's selling best, how sales are trending, how products are rated, where demand is concentrated, and which products risk stocking out. Across these, three findings stand out: a single hero product drives a disproportionate share of daily volume; demand follows a strong weekly (weekend-peak) cycle; and two regions account for nearly 30% of total demand — all of which have direct operational implications for inventory, staffing, and fulfillment planning covered in the sections below.

## 2. Objective

This report builds a descriptive analytics layer over daily purchase transactions to answer five recurring business questions:

- What are today's best-selling products?
- How are total sales trending day over day?
- How are products rated, and where is rating quality slipping?
- Where is demand concentrated geographically?
- Which products are at risk of stocking out?

Each question maps to one recurring stakeholder need — merchandising wants best-sellers, finance wants the revenue trend, customer experience wants rating quality, operations wants regional demand, and supply chain wants inventory risk. A single descriptive layer, refreshed daily, is designed to serve all four teams from one consistent source of truth rather than four separate ad-hoc reports.

## 3. Methodology & Assumptions

Since live transaction data isn't accessible for this exercise, a synthetic dataset was generated to mirror realistic e-commerce patterns rather than to represent any real Flipkart figures. The generation followed these assumptions:

- 60 individual products spread across 10 categories, sized to reflect a mid-sized marketplace catalog rather than the full platform
- 8 demand regions, each assigned a baseline demand share plus random daily noise
- 30-day window with a weekly seasonality component layered on top of a gradual linear trend, plus random noise per day, to mimic real weekday/weekend purchase cycles
- Ratings drawn from a distribution centered at 4.2/5 with realistic spread, rather than a uniform or extreme distribution
- Inventory tiers assigned so the vast majority of products stay in a healthy buffer, with a small minority landing in Low Stock or Out of Stock — consistent with typical catalog health in a well-managed marketplace

All figures in this report should be read as illustrative of pipeline output and chart structure, not as actual Flipkart performance data.

## 4. How This Would Work at Real Scale

Processing millions of purchases daily is an engineering problem before it's an analytics one. A realistic architecture:

| Layer                    | Purpose                                                      | Typical Tools              |
|--------------------------|--------------------------------------------------------------|----------------------------|
| <b>Investigation</b>     | Research, understand and reconstruct the transaction dataset | Google, Claude & ChatGPT   |
| <b>Extraction</b>        | Recover row-level records from the exported PDF export       | Python (pdfplumber, regex) |
| <b>Storage</b>           | Retain raw and cleaned data                                  | CSV / Excel files          |
| <b>Batch aggregation</b> | Category, city and behavioral KPIs                           | Python (pandas)            |
| <b>Report</b>            | Present analysis, graphs and insights                        | Matplotlib / MS Word       |

The report below reflects the output of that pipeline — daily aggregated tables — not raw event-level data, since no dashboard renders millions of individual rows usefully.

## 5. Daily Sales Trend

Over the simulated 30-day window: ~5.0 million units sold, generating ~\$623M in revenue, with a weekly seasonal cycle (mid-week dips, weekend peaks) layered on top of gradual category-level growth or decline trends per product.

### KPI definitions used:

- Daily units sold = sum of quantity across all completed orders that day
- Daily revenue = sum of (unit price × quantity) at time of sale, net of the aggregation layer (returns/cancellations would net out separately)

The recurring four-cycle pattern visible in the chart — roughly one peak every 7 days — is the clearest signal in the dataset. In a production setting, this rhythm would directly inform staffing rosters, warehouse pick-pack scheduling, and paid-

marketing pacing, since pushing promotional spend into an already-strong weekend adds less incremental lift than smoothing demand into the midweek trough.

Viewed as a running total instead of day-by-day, the same data shows a steady, near-linear climb to ~\$623M by day 30 — confirmation that growth is broad-based across the month rather than driven by one or two outlier days:

## 6. Best-Selling Products (Most Recent Day)

The top performer led with 18,259 units in a single day — nearly 50% ahead of the second-place product, a common “hero product” pattern in marketplaces where a small number of listings drive a disproportionate share of volume (a Pareto effect worth flagging for inventory prioritization).

Ranking logic: units sold, not revenue — a \$9 item outselling a \$200 item in volume matters differently to warehousing than it does to finance, so both cuts (units and revenue) should exist as separate leaderboard views in a real dashboard.

The drop-off from #1 to #8 is steep but not a cliff, which suggests healthy demand across the catalog rather than reliance on one product alone. Still, the #1 product alone approaches 11% of that day's total volume (see Section 12), which is the kind of

concentration that warrants its own dedicated reorder and quality-monitoring workflow rather than being folded into general catalog management.

## 6a. Category-Wise Sales Breakdown

Zooming out from individual products to the 10 product categories shows where volume concentrates at the category level: Electronics and Home & Kitchen lead, together accounting for close to a third of total units, while the remaining eight categories form a gradually declining long tail.

This view complements the individual best-seller list (Section 6) — a category can be strong even without a single standout hero product, which matters for category-level marketing and buying decisions as opposed to product-level inventory decisions.

## 7. Rating Distribution

Average rating across all product-days: 4.2 / 5, clustered tightly (most mass between 3.7–4.7). In a real system, this view is most useful segmented, not aggregated:

- Products trending downward in rolling 7-day average rating — the earliest signal of a quality or fulfillment issue
- Products with high sales volume but sub-4.0 ratings — the highest-risk combination, since volume amplifies the damage of poor reviews

A tight distribution is generally good news, but it also means the average has little room to absorb a real quality problem — a cluster of 1- and 2-star ratings on even one high-volume product would pull the aggregate down faster than the shape of this chart might suggest. This is why segment-level (not just aggregate) rating tracking matters more as sales volume grows.

Plotting rating against sales volume per product tests this directly: the trend line is only mildly downward-sloping, meaning high-volume products are not, on the whole, rated meaningfully worse than low-volume ones — a reassuring sign, though the handful of high-volume, sub-4.0 points on the right side of the chart are exactly the ones worth watching first.

## 8. Regional Demand

Demand distribution across regions was fairly balanced in this simulation (South Asia and Latin America led at ~710K and ~685K units respectively), which reflects the synthetic generation process. In practice, regional demand is rarely this even — real Flipkart-scale data typically shows heavy concentration in 2–3 core markets, with the rest long-tailed. This view is what drives:

- Regional warehouse/fulfillment center allocation
- Localized pricing and promotion decisions
- Shipping SLA risk (demand spikes in regions with limited local inventory)

Even in this relatively even simulation, the top 2 regions already account for close to 30% of total demand (Section 12). At real-world concentration levels, that share would likely be materially higher — reinforcing that regional fulfillment capacity, not aggregate national capacity, is the binding constraint operations teams should plan against.

## 9. Inventory Status

Inventory was bucketed into three tiers:

| Tier                    | Meaning              | Action                                |
|-------------------------|----------------------|---------------------------------------|
| In Stock                | Comfortable buffer   | None                                  |
| Low Stock (< 200 units) | Reorder trigger zone | Cross-check against best-seller list  |
| Out of Stock            | Lost-sale risk       | Prioritize if product is a top seller |

**Inventory Status — 60 Products**

The most actionable version of this chart in production cross-tabs inventory status against sales velocity, producing a “days of supply remaining” metric per product rather than a static stock count.

## 10. Key Insights

Reading the charts above together surfaces a few actionable patterns:

- Hero product dependency: the top product (Wireless Earbuds) sold ~18,259 units in a day — nearly 50% ahead of the #2 product and roughly 11% of that day's total volume. A stockout on this single product would materially dent daily revenue; it should sit at the top of the inventory-priority list, not be treated the same as a slow mover.
- Weekend-driven demand cycle: units sold swing ~35-40% between weekday troughs and weekend peaks. Staffing, delivery-slot capacity, and reorder timing should be planned around this weekly rhythm rather than a flat daily average.

- Regional concentration risk: South Asia and Latin America together account for ~29% of total demand. Fulfillment-center capacity and shipping SLAs in these two regions carry outsized impact if disrupted — worth a dedicated contingency plan.
- Rating quality is healthy but narrow: the 4.2/5 average is tightly clustered (3.7-4.7), meaning there's little cushion — a handful of high-volume products slipping below 4.0 could pull the aggregate down quickly. Segmenting by 7-day rolling rating (as noted in Section 7) would catch this before it shows up in the headline number.
- Inventory is largely healthy, but the at-risk products matter disproportionately: only 2 of 60 products (~3.3%) are Low Stock or Out of Stock, but if either is a top seller, the revenue impact is far larger than the product count suggests — this is where the best-seller list and inventory list should always be cross-checked together, not read in isolation.
- Revenue tracks volume closely, but not perfectly: the twin-axis trend chart (Section 5) shows units and revenue moving almost in lockstep across the 30 days, with an average selling price of ~\$124.85. That tight correlation is a good sign — it means pricing has stayed stable rather than revenue being propped up by a few high-price outliers — but any future divergence between the two lines would be an early flag that discounting or category mix is shifting.
- The catalog isn't overly reliant on the hero product alone: while the #1 product (Wireless Earbuds) leads by a wide margin, products ranked #2 through #8 in Section 6 still collectively out-sell it several times over. That's a healthier merchandising mix than a pure hero-product dependency would suggest — the risk flagged in the first insight above is real, but it sits alongside a reasonably diversified long tail worth preserving as the catalog grows.

## 10a. Additional Keywords & Insights

**Extending the analysis across the five theme areas in the report title — best-sellers, sales trends, ratings, regional demand, and inventory — surfaces seven further patterns:**

- Category diversity among best-sellers: the top 8 products by volume span multiple categories — electronics, home essentials, fitness, and accessories — rather than one vertical. Demand strength is broad-based, not dependent on a single category staying popular.
- Long-tail regions still matter: even the lowest-ranked regions, East Asia (~520K units) and Africa (~480K units), each move more volume in 30 days than the top single product sells in a day. Under-served regions are large enough that skipping them in expansion planning would leave real, sizeable demand unmet.
- Rating stability under scale: the 4.2/5 average held steady across ~5 million units sold over the month. Quality did not visibly erode as volume scaled — a sign that fulfillment and QC processes are keeping pace with growth, which is not guaranteed by default and is worth monitoring as volume rises further.
- Reorder cadence should not be uniform: with only ~3.3% of the catalog needing active reorder attention, reviewing the full catalog on the same weekly schedule wastes analyst time. A tiered cadence — daily checks for hero and at-risk products, monthly for the stable majority — would be a more efficient use of the same review effort.
- A growth trend sits beneath the weekly cycle: beyond the weekend peaks and midweek troughs, the 30-day trend line drifts gradually upward. That points to underlying demand growth independent of the weekly seasonality — worth isolating with a trend-decomposition model rather than attributing all movement to the weekend effect.
- Revenue concentration likely mirrors volume concentration: because average selling price stays fairly stable across the top sellers, the unit concentration in the hero product (Section 6) very likely carries through to a similar revenue concentration. A pricing or promotion misstep on that one product would hit the P&L harder than its single-product status suggests.
- Platform-wide cadence alignment: the weekend demand cycle likely holds across categories and regions alike, not just in the aggregate. Inventory replenishment, staffing, and delivery-slot capacity are better synchronized to one shared weekly rhythm platform-wide than optimized separately by department.

## 11. Explanation of Analysis — How Each Insight Was Derived

For transparency, this section walks through the reasoning and calculation behind each insight in Section 10, so the logic can be checked or reproduced against a real dataset:

- Hero product dependency (10.1): calculated by taking the top-selling product's single-day unit count (18,259) as a percentage of that day's total volume across the catalog (~166K units/day average) —  $18,259 \div 166,000 \approx 11\%$ . The comparison against the #2 product simply subtracts and divides  $(18,259 - 12,430) \div 12,430 \approx 47\%$ , rounded to “nearly 50%.”
- Weekend-driven demand cycle (10.2): read directly off the peaks and troughs in the Daily Sales Trend chart (Section 5) — weekday lows sit around 125K–140K units while weekend highs reach 185K–205K units, a swing of roughly 35–40% depending on the week.
- Regional concentration risk (10.3): the top two regions' unit totals (South Asia 710K + Latin America 685K = 1.395M) are divided by the sum of all 8 regions (~4.785M) —  $1.395M \div 4.785M \approx 29\%$ , matching the figure shown in the Percentage-Based Indicators chart (Section 12).
- Rating quality being narrow (10.4): based on the spread of the Rating Distribution histogram (Section 7), where roughly 90% of the mass falls between 3.7 and 4.7 around a 4.2 mean — a visibly tight, low-variance distribution rather than a wide or bimodal one.
- Inventory risk disproportion (10.5): straightforward ratio — 2 at-risk products  $\div$  60 total products  $\approx 3.3\%$ , cross-referenced conceptually (not numerically) against the best-seller list, since the report's synthetic data doesn't flag which specific products are low/out of stock.
- Revenue-volume correlation (10.6): observed qualitatively by comparing the shape of the two lines in the Daily Sales Trend chart — they rise and fall together on nearly every one of the 30 days, and ASP is derived simply as total revenue  $\div$  total units ( $\$623M \div 4.99M \approx \$124.85$ ).
- Long-tail catalog health (10.7): summed the unit counts of products ranked #2–8 in the Best-Selling Products chart (Section 6) —  $12,430 + 10,870 + 9,640 + 8,920 + 8,210 + 7,430 + 6,850 = 64,350$  units, several times the #1 product's 18,259 — showing volume isn't concentrated in one item alone despite its individual lead.

### 11a. Notes on the Additional Keywords (Section 10a)

- Category diversity: read directly off the product labels in the Best-Selling Products chart (Section 6) — Wireless Earbuds and BT Speaker (electronics), Kitchen Scale and Water Bottle (home/kitchen), Yoga Mat (fitness), Phone Case and Backpack (accessories) confirm the top 8 span at least three distinct categories.
- Long-tail regions: taken directly from the Regional Demand chart (Section 8) — East Asia (520K) and Africa (480K) are each roughly 28–29 $\times$  larger than the single-day top-seller figure of 18,259 units, which is the basis for the “more volume than a single product's best day” comparison.

- Rating stability: cross-references the flat 4.2 average in Section 7 against the ~4.99M total units in Section 12 — the same average holding across a 30-day, multi-million-unit window is the basis for calling it “stable under scale” rather than assuming stability, since ratings often drift as volume grows.
- Tiered reorder cadence: derived from the 3.3% at-risk share already calculated in 10.5 — the recommendation itself (daily vs. monthly review) is a suggested operating practice, not a figure pulled from the dataset.
- Growth trend beneath seasonality: a qualitative read of the Daily Sales Trend chart (Section 5) — each successive weekly peak sits slightly higher than the last (visible comparing day ~4, ~11, ~18, ~25), separate from the up-down weekly swing itself.
- Revenue concentration mirroring volume: an inference, not a direct measurement — built on the stable ASP observed in 10.6; since price-per-unit doesn't vary much across top sellers, a product's unit-volume share and its revenue share should track closely, though the report's data doesn't break out revenue per product to confirm this exactly.
- Platform-wide cadence: an extrapolation from the aggregate weekly cycle in Section 5 — the report's data is not broken out by category-by-day or region-by-day, so this is a reasonable operating hypothesis to test against real data rather than a figure confirmed in this dataset.

## 12. Summary of Key Metrics

|                                        |                   |
|----------------------------------------|-------------------|
| Total units sold (30 days)             | ~4.99M            |
| Total revenue (30 days)                | ~\$623M           |
| Average Selling Price (ASP)            | ~\$124.85 / unit  |
| Average daily units sold               | ~166K units/day   |
| Average product rating                 | 4.2 / 5           |
| Top single-day seller                  | 18,259 units      |
| Hero product share of top day's volume | ~11%              |
| Weekend-to-midweek demand swing        | ~35-40%           |
| Top 2 regions' share of total demand   | ~29%              |
| Regions tracked                        | 8                 |
| Products at Low Stock or below         | 2 of 60 (~3.3%)   |
| Product categories tracked             | 10                |
| Total catalog size                     | 60 products       |
| Peak single-day revenue                | ~\$26.1M (Day 24) |
| Lowest single-day revenue              | ~\$16.1M (Day 8)  |
| Core rating range                      | 3.7 – 4.7 / 5     |
| In-Stock products                      | 58 of 60 (~96.7%) |
| Long-tail (#2–#8) combined volume      | 64,350 units      |

## Total Volume & Revenue

## Daily Activity Snapshot

## Pricing & Rating

## Percentage-Based Indicators

## Additional Key Metrics — Scope, Revenue Range, Rating &amp; Inventory

## Catalog Scope

## Daily Revenue Range

## Core Rating Range

## Inventory Health (of 60)

## 13. Next Steps to Move From Descriptive → Predictive

This report answers what happened. The natural next layer, if useful:

- Demand forecasting per product/region to set reorder points automatically
- Anomaly detection on rating drops or sudden demand spikes
- Cohort/retention analysis on repeat purchase behavior, not just unit counts

*Next: build out any of the above, or swap in a real dataset (CSV/Excel export, a database connection, etc.) — the same pipeline and chart structure above would apply directly.*

## 14. Appendix

### A. Sample Data Row Structure

Each raw transaction event feeding the pipeline (Section 4) is expected to carry, at minimum:

- order\_id, product\_id, category, region — identifiers
- unit\_price, quantity, order\_timestamp — transaction facts
- rating (if a review was left), rating\_timestamp — quality signal, nullable
- stock\_on\_hand, reorder\_threshold — inventory state at time of order

### B. Glossary of Terms

- ASP (Average Selling Price): total revenue ÷ total units sold over a given period
- Hero product: a single product responsible for a disproportionately large share of daily volume
- Long tail: the group of lower-ranked products or regions that, while individually smaller, collectively represent significant volume
- SLA (Service-Level Agreement): a committed standard for delivery time or fulfillment performance
- Days of supply: current stock on hand ÷ average daily sales rate, i.e. how many days until a product runs out at the current pace

### C. Report Scope Summary

- Window: 30 simulated days
- Catalog: 60 products across 10 categories

- Geography: 8 regions
- Prepared for: academic / demonstration purposes only — not actual Flipkart data

# Thank You

Thank you for reading this report.
